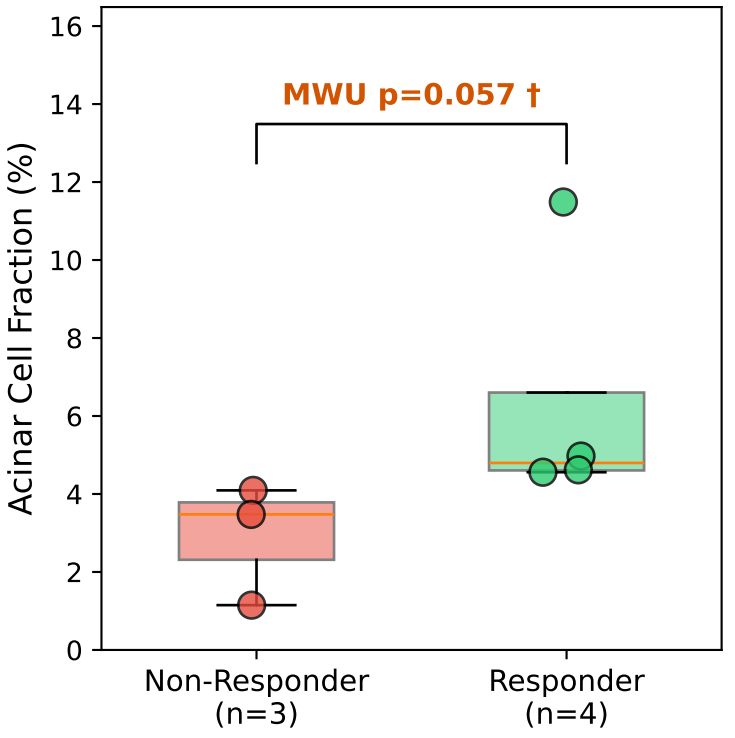
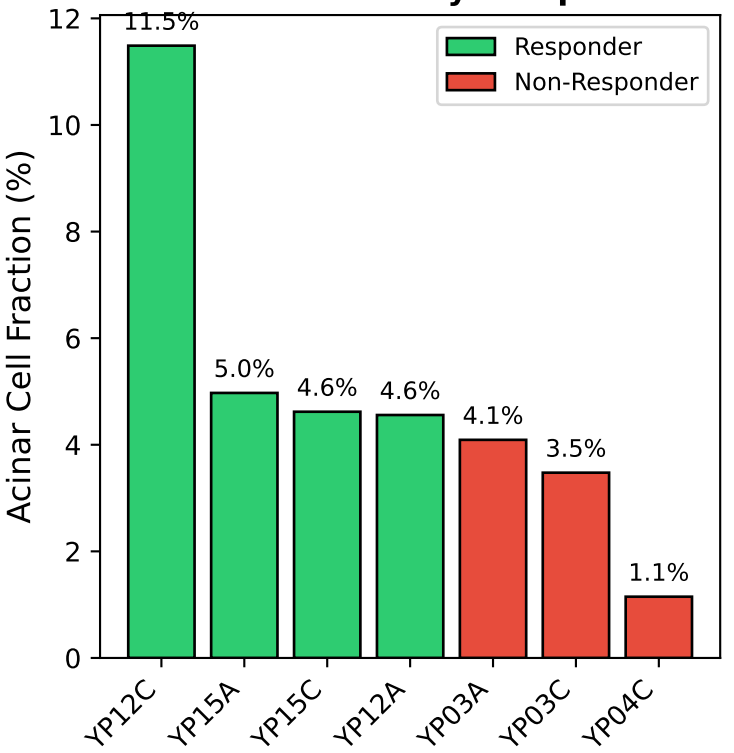
ACINAR CELL ENRICHMENT IN TREATMENT RESPONDERS
Pancreatic Ductal Adenocarcinoma (PDAC) Spatial Transcriptomics Analysis

A. Acinar Enrichment in Responders



B. Acinar % by Sample



C. Statistics & Interpretation

```
STATISTICAL ANALYSIS
========================================

Sample Sizes:
  • Responders (R): n = 4
  • Non-Responders (NR): n = 3

Acinar Cell Fractions:
  • R Mean: 6.4% (SD: 2.9%)
  • NR Mean: 2.9% (SD: 1.3%)
  • Difference: +3.5%

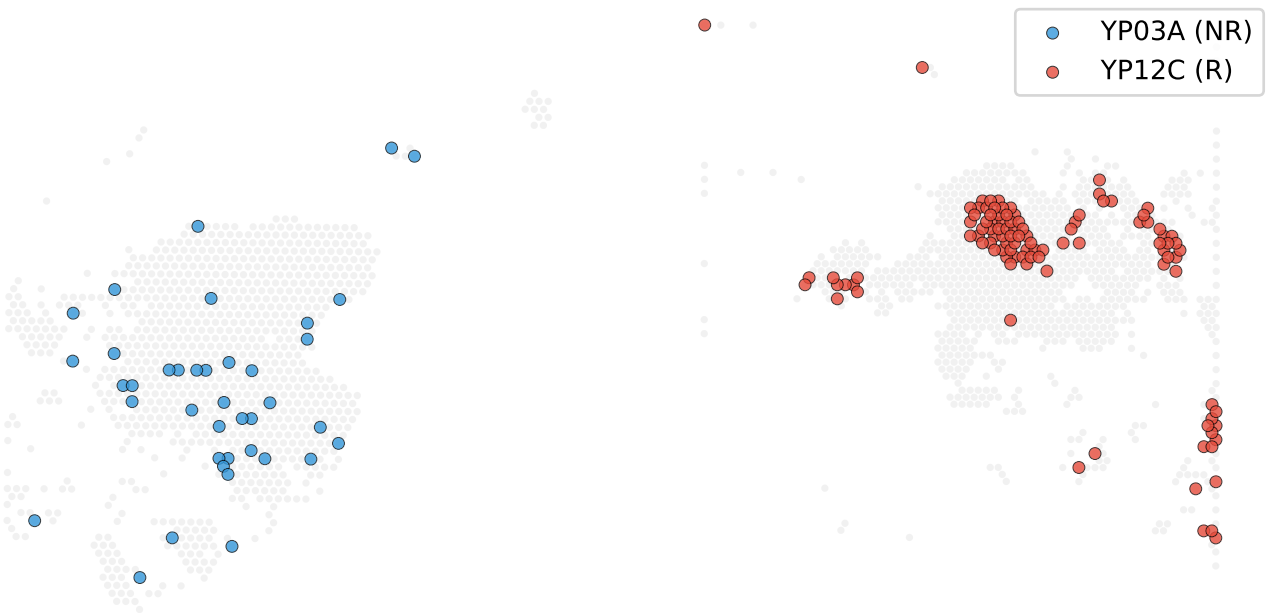
Statistical Tests:
  • Mann-Whitney U: p = 0.0571 †
  • Welch's t-test: p = 0.1352

========================================
INTERPRETATION
========================================

Acinar cells show a TRENDING increase in
treatment responders (p=0.057).

This finding suggests that preserved acinar
cell populations may be associated with
better treatment outcomes in PDAC.
```

D. Spatial Distribution of Acinar Cells
(Red/Blue = Acinar cells, Gray = Other cells)



E. Conclusions

Note: With n=4 R and n=3 NR, statistical power is limited. This finding warrants validation in larger cohorts.

```
KEY FINDING
═══════════

Acinar cells are the ONLY cell type
showing a trending difference between
treatment responders and non-responders.

• 2.2x higher in Responders
  (6.4% vs 2.9%)

• MWU p = 0.057 (trending)

BIOLOGICAL SIGNIFICANCE
═══════════════════════

Acinar cells are the primary functional
cells of the exocrine pancreas. Their
preservation may indicate:

1. Less tumor infiltration
2. Better tissue architecture
3. Maintained organ function

This could explain better treatment
response through improved drug delivery
and immune cell access.

NEXT STEPS
══════════

• Validate in independent cohort
• Correlate with clinical outcomes
• Investigate spatial relationships
  with immune cells
```
